Introduction

- Growth references show how children grow in a particular population (genetic background), at a particular time (changing environment)
- Used to monitor overall health and wellbeing
- Children with conditions known to affect growth usually excluded
- Overweight/obese children:
 - Height also different
 - Increasing prevalence →
 - **Also exclude?**

Figure 1. Prevalence of overweight among children and adolescents ages 6-19 years

NOTE: Excludes pregnant women starting with 1971-74. Pregnancy status not available for 1963-65 and 1966-70. Data for 1963-65 are for children 6-11 years of age; data for 1966-70 are for adolescents 12-17 years of age, not 12-19 years. SOURCE: CDC/NCHS, NHES and NHANES

Materials and Methods (1)

- Cross-sectional data from 2 growth reference studies
- 12252 Belgian and 6159 Norwegian children
- 2 – 18 years of age
- Measured (height, weight → BMI) in 2002–2006
- Weight status defined by IOTF¹:

not overweight, overweight (excl. obese), obese

¹Cole et al. BMJ, 2001

Materials and Methods (2)

1) Is height different in these “*weight classes*” ?

- height (cm) → SD scores
- anova within age groups (both sexes combined)

2) Are height-by-age references affected?

- Three height reference curves estimated:
 - All children (=current national reference)
 - Excluding *obese* children only
 - Excluding *overweight* and *obese* children
- LMS method², same # edf

²Cole and Green, Stat. Med. 1992

KU LEUVEN

Conclusion

- Typical height pattern confirmed:
 - Overweight and obese children are on average taller before puberty
 - Earlier maturity?
- Similar effect on the growth chart when excluding children with overweight or obesity
 - Effect of additional exclusion depends on *effect size* and *prevalence*: larger for overweight!
 - Could be larger in populations with higher prevalence
- Minor consequences for clinical cut-offs

Should we exclude children with overweight or obesity from height reference samples?
